

## Simeprevir

Updated: February 7, 2022.

## OVERVIEW

### Introduction

Simeprevir is an oral, direct acting hepatitis C virus (HCV) protease inhibitor that is no longer available but was previously used in combination with other antiviral agents in the treatment of chronic hepatitis C, genotypes 1 and 4, but subsequently was withdrawn. Simeprevir has been linked to isolated, rare instances of mild, acute liver injury during treatment and to occasional cases of hepatic decompensation in patients with preexisting cirrhosis.

### Background

The hepatitis C virus is a small RNA virus that is a major cause of chronic hepatitis, cirrhosis and hepatocellular carcinoma in the United States as well as worldwide. Various approaches to antiviral therapy of chronic hepatitis C have been developed, starting in the 1980s with interferon alfa which was replaced in the 1990s by long acting forms of interferon (peginterferon), to which was added the oral nucleoside analogue, ribavirin. Between 2010 and 2015, several potent oral, direct acting anti-HCV agents were developed and combinations of these found to have marked activity against the virus, allowing for highly effective therapy without use of interferon with treatment courses of 12 to 24 weeks only. These direct acting agents included HCV protease (NS3/4) inhibitors, structural replication complex (NS5A) inhibitors and the HCV RNA polymerase (NS5B) inhibitors.

Simeprevir (sim e' pre vir) was the third HCV protease inhibitor to become clinically available for therapy of hepatitis C. Like other HCV protease inhibitors, simeprevir blocks the activity of the viral encoded protease (HCV nonstructural [NS] region 3/4) that is essential in the posttranslational modification of the viral polypeptide that is cleaved into a series of structural and nonstructural (enzyme) regions. When used by itself, simeprevir results in rapid inhibition of HCV RNA levels, but resistance develops rapidly in a high proportion of patients. When combined with peginterferon and ribavirin, it was shown to provide a sustained inhibition of HCV RNA with a low rate of antiviral resistance. When given for 24 to 48 weeks, triple therapy using simeprevir increased the sustained virological response (SVR) rate from 40% to 50% (peginterferon and ribavirin alone) to 65% to 75% in patients with genotype 1. Even higher rates of response were found when simeprevir was combined with the HCV polymerase inhibitor sofosbuvir in an all-oral, interferon free regimen for 12 weeks. Simeprevir was approved for use in the United States in 2013 for patients with chronic hepatitis C, genotypes 1 and 4, in combination with peginterferon and ribavirin or as an all-oral regimen with sofosbuvir. It was voluntarily withdrawn by the sponsor in 2018 because of availability of other highly effective regimens for hepatitis C consisting of fixed doses in single tablet formulations. Interestingly, simeprevir has been shown to have antiviral activity against SARS-CoV-2 but has not been assessed in clinical cases of COVID-19. Simeprevir was previously available in 150 mg capsules under the brand name Olysio (formerly TMC435), and the

recommended dose was 150 mg once daily for 12 weeks. Common side effects included rash, photosensitivity, pruritus, nausea, headache, muscle aches and abdominal discomfort.

## Hepatotoxicity

In large randomized controlled trials, simeprevir was not linked to an increased rate of serum enzyme elevations during treatment or with instances of clinically apparent liver injury. Simeprevir can cause a mild increase in indirect bilirubin and some patients become visibly jaundiced; but the bilirubin elevations were generally mild, transient and not associated with changes in serum aminotransferase or alkaline phosphatase levels. After its approval and more wide scale use, however, simeprevir was implicated in at least one case of an acute hepatitis (Case 1). The latency to onset was 7 weeks and pattern of injury was hepatocellular without immunoallergic or autoimmune features. Recovery was rapid once therapy was stopped.

In addition, simeprevir, in combination with other agents, has been linked to instances of acute, seemingly spontaneous decompensation of HCV related cirrhosis. The role of simeprevir as opposed to the other HCV antivirals used in combination was often unclear. Rates of hepatic decompensation during simeprevir combination therapy of cirrhosis due to hepatitis C was approximately 2% to 3% when combined with peginterferon and ribavirin, and 0.5% to 1.0% when used with sofosbuvir. Because of the risk of decompensation, patients with cirrhosis who are treated with antiviral regimens (both all-oral and interferon based) should be monitored for evidence of worsening liver disease, particularly during the first 4 weeks of treatment. This complication is probably more common in patients with more advanced liver disease, Child's Class B cirrhosis and those with a previous history of liver decompensation.

In addition, direct acting antiviral therapy of hepatitis C including regimens using simeprevir have been linked to instances of reactivation of hepatitis B with rise or denovo appearance of HBV DNA in serum followed by a flare of hepatitis that can be severe. The rate of reactivation is appreciable in patients with HBsAg and HBV DNA in serum, but also can occur rarely in persons without HBsAg but with anti-HBc in serum. For these reasons, screening for hepatitis B is recommended in patients who are to receive antiviral therapy of chronic hepatitis C.

Likelihood score: B (likely cause of clinically apparent liver injury usually manifesting as hepatic decompensation in patients with preexisting cirrhosis and probable rare cause of reactivation of hepatitis B in susceptible patients).

### Mechanism of Injury

The mechanism by which simeprevir might cause liver injury is not known. It is metabolized in the liver largely via the cytochrome P450 system, predominantly CYP 3A and it is an inhibitor of the drug transporters P-glycoprotein and OATP1Ba/3 and the efflux transporters MDR1, MRP2 and BSEP, perhaps accounting for the indirect hyperbilirubinemia that occurs in some patients. Simeprevir is associated with drug-drug interactions and it can raise levels of some statins. The decompensation that occurs with simeprevir combination therapy may be due to a direct effect of the agent, or else represent a usual complication of the rapid eradication of HCV infection. Finally, the episodes of decompensation may be incidental and unrelated to the antiviral therapy.

## Outcome and Management

Combination antiviral regimens with peginterferon and ribavirin are now rarely used, largely because of the superior efficacy and better tolerance of all-oral regimens for hepatitis C. The oral regimen of sofosbuvir and simeprevir, while highly effective, is more expensive than other equally effective oral regimens and simeprevir is no longer available in the United States. Simeprevir in combination with other antiviral agents has been associated with cases of decompensation in patients with preexisting cirrhosis and with reactivation of hepatitis B in patients with ongoing or previous HBV infection.

Because of the risk of hepatic decompensation in patients with preexisting cirrhosis, particularly those with a prior history of hepatic decompensation, regular monitoring is recommended for patients with hepatitis C related cirrhosis undergoing antiviral therapy, particularly during the first 4 weeks. Therapy should be suspended if signs or symptoms of hepatic failure arise such as marked rises in serum bilirubin (both direct and indirect) and any worsening of ascites, hepatic encephalopathy or prolongation of the prothrombin time. Antiviral therapy of hepatitis C is also a risk factor for reactivation of hepatitis B, and screening for HBsAg and anti-HBc before starting antiviral therapy is recommended. Those with evidence of ongoing or previous HBV infection should be treated prophylactically with antiviral agents with potent activity against HBV or monitored with tests for HBV DNA and started on anti-HBV therapy if levels rise.

## CASE REPORTS

### Case 1. Acute hepatitis during therapy of chronic hepatitis C with simeprevir, peginterferon and ribavirin.(1)

A 65 year old Japanese man with chronic hepatitis C, genotype 1b, developed fatigue and abdominal bloating and was found to have worsening of serum aminotransferase levels 49 days after starting triple antiviral therapy with simeprevir [100 mg orally, once daily], peginterferon [100 µg subcutaneously, each week] and ribavirin [400 mg orally, twice daily]. Serum ALT which had fallen on antiviral therapy rose to 768 U/L with a serum bilirubin of 3.3 mg/dL, alkaline phosphatase 171 U/L, INR 1.2 and albumin 3.8 g/dL (Table). He had no previous history of liver disease other than hepatitis C which was attributed to a blood transfusion 45 years previously and for which he had not been previously treated. He also had a history of heavy alcohol use, but had stopped five years previously. His other medical conditions included diabetes for which he was taking voglibose (an alpha glucosidase inhibitor) and glimepiride (a sulfonylurea), and hyperuricemia for which he was taking allopurinol. All of his medications he had taken for more than a year and he denied use of other over-the-counter medications or nutritional or herbal supplements. Physical examination showed no evidence of fever or rash, and an eosinophil count was normal (1.2%). Tests for hepatitis A, B, C and E were negative as were tests for acute EBV and CMV infection. Both ANA and SMA were negative and serum globulins were not elevated. Imaging of the liver by ultrasound showed no evidence of biliary obstruction or masses. A liver biopsy showed evidence of acute hepatocellular injury superimposed upon on chronic hepatitis, but did not suggest autoimmune hepatitis. Antiviral therapy was suspended, and he improved rapidly. One month later, his symptoms had resolved and all liver tests, including ALT levels, were normal. He remained HCV RNA negative and was ultimately considered to have a sustained virologic response despite the early discontinuation of therapy.

### Key Points

Medication:	Simeprevir, peginterferon and ribavirin
Pattern:	Hepatocellular (R ratio=18)
Severity:	Moderate (jaundice and hospitalization)
Latency:	7 weeks
Recovery:	1 month
Other medications:	Ursodiol, voglibose, glimepiride and allopurinol chronically

## Laboratory Values

Time After Starting	Time After Stopping	ALT (U/L)	Alk P (U/L)	Bilirubin (mg/dL)	HCV RNA (IU/mL)	Other
Day 0	0	301	185	1.6	1.3 million	Therapy started
Week 4	0	23		1.7	None	Routine monitoring
Week 7	0	768	171	3.3	None	Admission
Week 12	5 weeks	20	166	1.1	None	Asymptomatic
<b>Normal Values</b>		<b>&lt;40</b>	<b>&lt;360</b>	<b>&lt;1.2</b>	<b>None</b>	

## Comment

A man with known chronic hepatitis C for many years developed an asymptomatic worsening of disease with ALT rising to 301 U/L, for which reason he was started on combination therapy of simeprevir with peginterferon and ribavirin, a regimen that was available and approved for use in Japan. He did well for the first six weeks of treatment and was HCV RNA negative when tested at 4 weeks. After 7 weeks, however, he developed nonspecific symptoms of fatigue and was found to have marked elevations in ALT and mild jaundice. Thorough evaluation found no evidence of other forms of liver disease and he was, indeed, still negative for HCV RNA. He improved rapidly once antiviral therapy was stopped and all liver tests had returned to normal one month later. Fortunately, his HCV infection did not relapse and he appeared to have achieved an SVR with other 7 weeks of treatment. This was a very convincing case of liver injury due to the antiviral therapy. Because he was receiving three agents, one cannot say for sure which one was responsible, but attributing it to simeprevir appears appropriate.

## Case 2. Acute hepatic decompensation in a patient with chronic hepatitis C and cirrhosis during therapy with simeprevir and sofosbuvir.(2)

A 56 year old man with chronic hepatitis C, genotype 1a, and Child's Class B cirrhosis developed worsening fatigue, anorexia and jaundice 4 weeks after starting oral therapy with simeprevir and sofosbuvir. He had a history of excessive alcohol use, but had stopped drinking years before. He had been treated with peginterferon and ribavirin for hepatitis C on two occasions in the past, without a significant response and had undergone transjugular intrahepatic portosystemic stent shunting (TIPSS) two years previously because of refractory ascites and esophageal varices. He was evaluated for liver transplantation, having a MELD score of 17 with serum bilirubin 5.3 mg/dL, ALT 29 U/L, INR not given. He received approval for pretransplant, compassionate use therapy with the oral antiviral regimen of sofosbuvir and simeprevir (doses not provided). He had a rapid virological response becoming HCV RNA negative by week 4. However, the total serum bilirubin level rose concurrently to 6.6 by week 2 and 28.0 mg/dL by week 4, at which point the antiviral drugs were stopped (Table). His MELD score subsequently rose to 36, the INR to 4.4 and he underwent successful emergency liver transplantation 4 weeks after stopping therapy. In follow up, he remained HCV RNA negative, suggesting a SVR despite therapy for only 4 weeks.

## Key Points

Medication:	Simeprevir and sofosbuvir
Pattern:	Unknown (alkaline phosphatase not given)
Severity:	Fatal (liver transplantation)
Latency:	4 weeks
Recovery:	None

Table continued from previous page.

Other medications:	None mentioned

8 Weeks	4 weeks	Normal	Normal	14.2	None	Liver transplantation
<b>Normal Values</b>		<b>Not Provided</b>		<b>&lt;1.2</b>	<b>None</b>	

## Comment

A man with chronic hepatitis C and cirrhosis and a past history of alcoholism presented for a liver transplant evaluation and was found to have advanced liver disease with moderate decompensation (Child's Class B). He had HCV genotype 1a infection and a history of "null" responses to courses of peginterferon and ribavirin. He was started on an oral regimen of simeprevir and sofosbuvir, which in clinical trials had been shown to yield sustained virological response rates of 73% in patients with Child's B cirrhosis. Indeed, he rapidly became HCV RNA negative, but had worsening symptoms and jaundice with rises in serum ALT and INR, prompting emergent liver transplantation. Fortunately, the antiviral therapy was successful in eradicating HCV infection and he remained HCV RNA negative thereafter. While somewhat short on details, this case report was reasonably convincing as demonstrating liver injury due to antiviral therapy. The authors attributed the injury to simeprevir, but sofosbuvir was given concurrently making it difficult to attribute the episode to one versus the other agent. Another possibility was that the sudden decompensation was triggered by the rapid clearance of HCV infection, as occurs in some cases of chronic hepatitis B during initiation of antiviral therapy. Finally, the decompensation may have been coincidental and not related to the drugs or antiviral response at all. Several such instances of "spontaneous" hepatic decompensation arising during potent antiviral therapy have been described which argues for careful monitoring of patients with cirrhosis, particularly during the first few weeks of therapy. This case also shows that antiviral therapy of patients with advanced cirrhosis is best left to centers with expertise in managing end stage liver disease and where liver transplantation is available.

## PRODUCT INFORMATION

### REPRESENTATIVE TRADE NAMES

Simeprevir – Olysio®

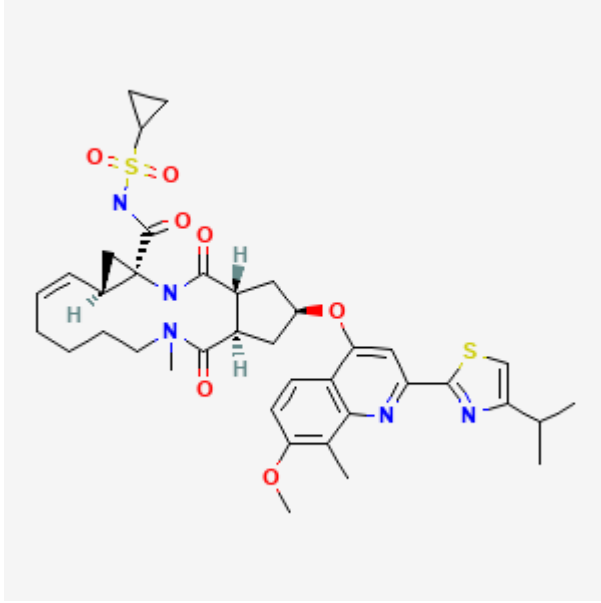

### DRUG CLASS

Hepatitis C Agents

### COMPLETE LABELING

Product labeling at DailyMed, National Library of Medicine, NIH
